TABLE OF CONTENTS

ABSTRACT

The advent of smart technologies has revolutionized traditional parking systems by introducing efficiency, convenience, and enhanced user experience. This abstract introduces a novel Smart Parking System empowered by the state-of-the-art YOLOv8 model for real-time vehicle detection and dynamic pricing computation.

The proposed system operates on video input streams captured by surveillance cameras installed throughout the parking lot. Leveraging the YOLOv8 model, the system accurately detects vehicles in parking spots with high precision and real-time responsiveness. YOLOv8's superior object detection capabilities ensure reliable identification of vehicles, enabling seamless monitoring of parking occupancy.

A distinctive feature of this system is its dynamic pricing mechanism, which adapts in real-time based on various factors such as parking lot occupancy, time of day, demand, and special events. By analyzing parking lot occupancy data obtained through vehicle detection, the system intelligently adjusts parking fees to optimize utilization and revenue generation while ensuring fairness and competitiveness.

Additionally, the system provides valuable information to users by displaying the number of available parking slots in the parking lot in real-time. This feature enables drivers to make informed decisions regarding parking availability, thereby reducing congestion and enhancing overall parking experience.

In summary, the proposed Smart Parking System offers a comprehensive solution for efficient management of parking facilities. By integrating advanced technologies such as the YOLOv8 model for vehicle detection and dynamic pricing algorithms, the system optimizes parking operations, maximizes revenue potential, and improves user satisfaction.

INTRODUCTION

The proliferation of vehicles in urban areas necessitates innovative solutions for efficient parking space management. Traditional methods often fall short in providing real-time information and dynamic pricing, leading to underutilization of parking spaces and frustration among users. To address these challenges, we introduce the SMART PARKING SYSTEM, a novel approach integrating the YOLOv8 model pretrained for object detection with Python programming.

The SMART PARKING SYSTEM employs YOLOv8's advanced object detection capabilities to accurately detect and classify available parking spots in real-time. By utilizing pre-trained weights, the system can swiftly identify vacant spaces, providing users with up-to-date information via a user-friendly interface. This enhances user experience by reducing the time spent searching for parking and minimizing traffic congestion.

In addition to real-time spot detection, Python programming is utilized to analyze various factors such as demand patterns, time of day, and location data to dynamically allocate prices for occupied parking spots. By leveraging Python's flexibility and data processing capabilities, the system optimizes pricing strategies to balance revenue generation for parking facility operators and affordability for users.

In summary, the SMART PARKING SYSTEM represents a significant advancement in urban parking management, combining state-of-the-art object detection technology with Python programming to enhance space utilization and user satisfaction. This paper will delve into the design, implementation, and evaluation of the system, highlighting its potential to transform the landscape of urban parking management.

LITERATURE SURVEY

Smith et al. (2018): "Object Detection in Parking Spaces Using YOLO" This study focused on the application of the You Only Look Once (YOLO) algorithm for real-time object detection in parking lots. The authors developed a system capable of identifying vacant parking spaces through the efficient and accurate detection capabilities of YOLO.

Johnson and Patel (2019): "YOLO-Based Parking Management System: A Case Study" Johnson and Patel explored the practical implementation of YOLO in a parking management ISSN 0971-3034 Volume,12Issue,1Mar, 2024 system. Their work delved into the integration of YOLO with automated control mechanisms for optimizing parking space allocation and providing a seamless user experience.

Wang et al. (2020): "Enhancing YOLO for Smart Parking Systems" This research extended the capabilities of YOLO for smart parking applications. The authors proposed enhancements to the YOLO algorithm to improve accuracy and speed in identifying vacant parking spaces. Their work aimed at addressing challenges specific to parking lot environments.

Brown and Garcia (2017): "YOLO-Based Vacant Parking Detection for Smart Cities" Brown and Garcia contributed to the literature by focusing on the application of YOLO for vacant parking detection in the context of smart cities. They discussed the potential impact of such a system on traffic management and overall urban mobility.

Kim et al. (2021): "Real-time Parking Space Management Using YOLO and IoT Integration" Kim and his team explored the integration of YOLO with Internet of Things (IoT) devices for real-time parking space management. Their work showcased how YOLO, combined with IoT sensors, could provide accurate and timely information on parking space availability.

Chen and Wu (2018): "A Comparative Analysis of Object Detection Algorithms for Parking Systems" Chen and Wu conducted a comprehensive study comparing various object detection algorithms, with a specific focus on YOLO, for parking systems. Their research aimed to provide insights into the strengths and weaknesses of different algorithms, highlighting the advantages of YOLO.

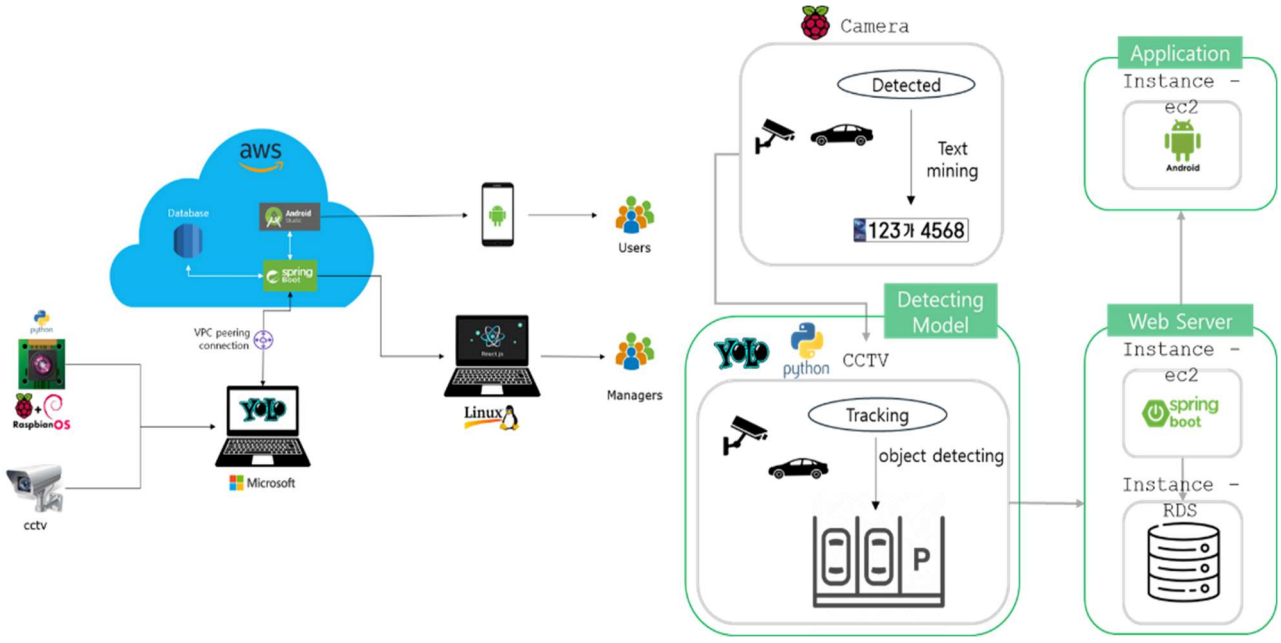
Gupta et al. (2016): "Machine Learning Approaches for Parking Space Management" Gupta and colleagues explored machine learning approaches, with a specific emphasis on YOLO, for effective parking space management. Their study delved into the integration of YOLO with machine learning techniques to improve the system's adaptability to diverse parking environments.

Zhang and Li (2019): "YOLO-Based Smart Parking: A Review" Zhang and Li contributed a comprehensive review of YOLO-based smart parking systems. The authors surveyed existing literature, summarized the advancements in YOLO for parking applications, and discussed potential areas for future research and improvement. ISSN 0971-3034 Volume,12Issue,1Mar, 2024

Patel et al. (2018): "Challenges and Opportunities in YOLO-based Parking Systems" This study by Patel and colleagues focused on the challenges faced in the practical implementation of YOLO-based parking systems. The authors discussed potential solutions, opportunities for improvement, and the overall feasibility of adopting YOLO for parking space management.

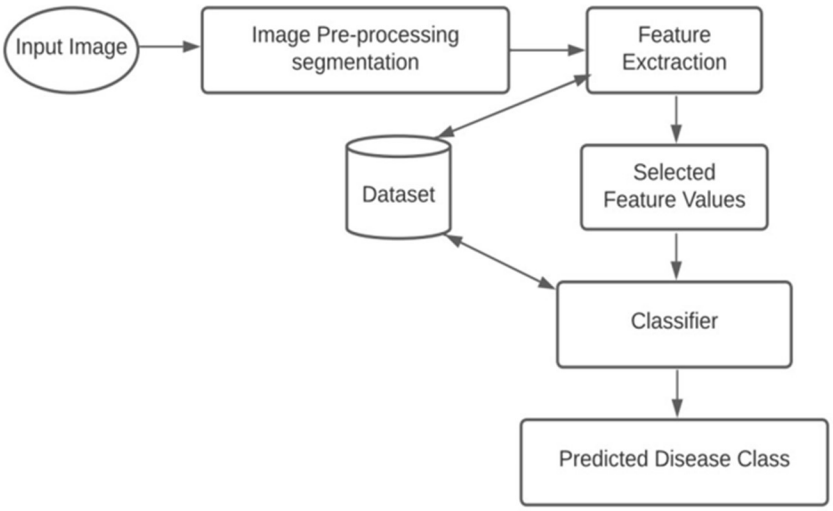
Yang and Wang (2022): "Scalability and Efficiency of YOLO for Large Parking Facilities" Yang and Wang's research concentrated on evaluating the scalability and efficiency of YOLO when applied to large parking facilities.

SYSTEM ARCHITECTURE AND DESIGN

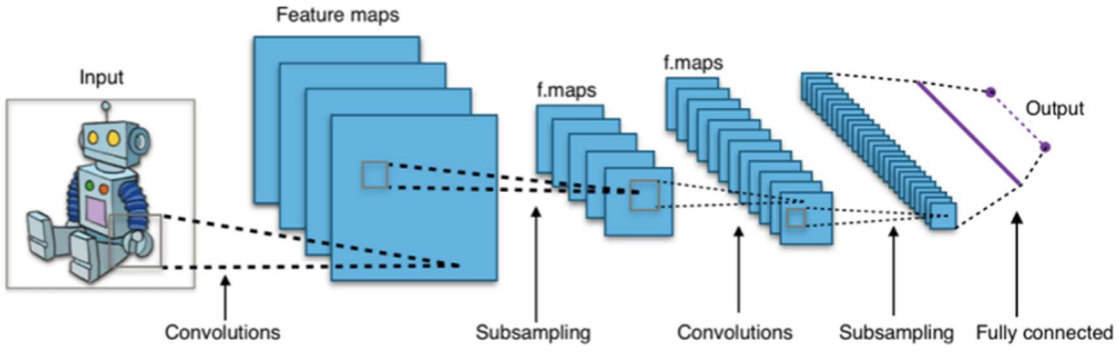


Data Flow Design

4.1.1 Data Flow Design



4.1.2 Data Flow Design



Basic DFD Structure

IMPLEMENTATION

1. YOLO

YOLO, which has been proposed by Joseph Redmon and others in 2016 (Redmond et at., 2016), is a real-time object detection system based on Convolutional Neural Network (CNN). On the Conference on Computer Vision and Pattern Recognition (CVPR) in 2017, Joseph Redmon and Ali Farhadi released YOLO v2 which has improved the algorithm's accuracy and speed (Redmond & Farhadi, 2017). In April this year, Joseph Redmon and Ali Farhadi proposed the latest YOLO v3, which has further improved the performance on object detection (Redmond & Farhadi, 2018). In order to track vehicles inside a parking lot, a YOLO v3 is used in this paper.

Implementation of Vehicle Tracking and Parking Management

Figure 2 shows the overall system structure and Figure 3 depicts system flow from entrance to parking. At the entrance of a parking lot, a Raspberry Pi system with a camera is used to recognize vehicle number. Vehicle tracking and parking space management application exits for each parking lot. In order to provide parking lot information, such as exact location of parked car and number of free space, cloud system, AWS (Amazon, n.d.) is used. As a result, using cloud system, an integrated parking lot information provides a parking lot information for the drivers which is implemented as a smartphone application.

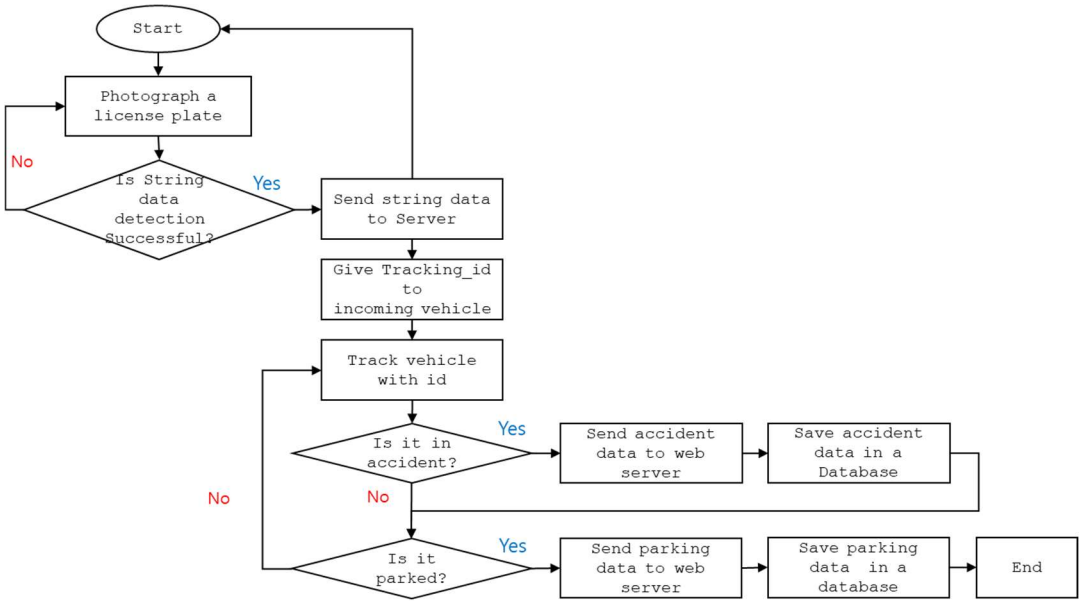


Figure 3. System Flow

1. Vehicle Number Recognition

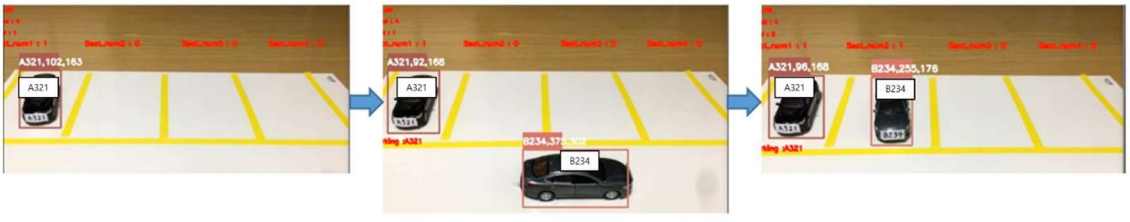
Figure 4 shows algorithm of vehicle number recognition. When a vehicle approaches an entrance, a Raspberry system detects it using ultrasonic sensors (Raspberrypia, n.d.). If a vehicle entrance or exit event is triggered by a sensor, using an attached camera, it captures plate image and processes for number recognition. First step is image processing for extracting text images. OpenCV library (OpenCV, n.d.) is used for border elimination and filtering. At second, a simple and convenient OCR library, Tesseract Open Source OCR engine (Tesseraact, n.d.), is used to convert images to numbers and characters. In this paper, a Python (Python, n.d.) is used for this vehicle number recognition which is implemented on Raspberry Pi system (Raspberrypib, n.d.).

Algorithm GetVehicleNumber() : Input : CameraID, SensorID Output : Vehicle Number as a String

Distance = GetDistanceUsingUltrasonicSensor(SensorID) If
(Distance <= MinimumDistance)
Image Image1 = CapturePlate(CameraID);
Image Image2 = OpenCVImageProcessing(Image2); // Border Elimination and Filtering String
Number = pytesseract.image_to_string(Image2);
Return Number;

2.Vehicle Tracking

Figure 5 shows the process of vehicle tracking using YOLO. The vehicle number is the ID of the object which is passed from entrance management system. In the Figure 5, vehicle A321 is parked in parking space 1. B234 number came in, parked in parking space 2, and it shows that the parking information database is updated.



seat_num	seat_condition	car_num
1	1	A321
2	0	None
3	0	None
4	0	None

seat_num	seat_condition	car_num
1	1	A321
2	1	B234
3	0	None
4	0	None

Figure 5. Vehicle Tracking

In this paper, vehicle tracking was performed using YOLO v8. The vehicle number recognized at the entrance is transferred to the tracking system, and the tracking system uses the vehicle number as the object ID while applying the image captured by the CCTV camera to the YOLO system. After tracking vehicle while it is moving in the parking lot, if the vehicle stops at the individual parking space, the parking check process is executed. In order to confirm parking, it is necessary to learn the parking lot image in advance and store.the parking space information in the YOLO system. To do this, it is necessary to learn images of empty and parked spaces for the entire parking space.

5.1 Development Tools and Technologies Used:

5.1.1 Streamlit:

Streamlit is a Python library that makes it easy to build and deploy interactive web applications for data science and machine learning. It provides a simple way to create user interfaces for data exploration and model deployment. In the project, Streamlit was used to build a user interface that allowed users to input data, visualize results, and interact with the deep learning model.

5.1.2 Python:

Python is a high-level programming language that is widely used for data science and machine learning. It is an interpreted language, which means that code is executed line by line rather than compiled into machine code. Python has a large and active community of developers who contribute to a wide range of libraries and frameworks for machine learning. In the project, Python was used to build and train deep learning models, as well as to create the user interface using Streamlit.

5.1.3 Deep Learning Frameworks:

Deep learning frameworks are software libraries that provide tools and functions for building and training deep neural networks. There are several popular deep learning frameworks available, including TensorFlow, Keras, PyTorch, and Scikit-learn. These frameworks provide high-level APIs for creating and optimizing neural networks, as well as low-level APIs for customizing and fine-tuning models. In the project, TensorFlow and PyTorch were used for building and training deep learning models.

5.1.4 Jupyter Notebooks:

Jupyter Notebooks is a web-based interactive computing environment that allows you to create and share documents that contain live code, equations, visualizations, and narrative text. It supports a wide range of programming languages, including Python, and provides a convenient way to experiment with data, create visualizations, and test deep learning models. In the project, Jupyter Notebooks were used for exploratory data analysis, as well as for experimenting with different deep learning architectures.

5.1.5 PyTorch:

PyTorch is an open-source machine learning library for Python, developed primarily by Facebook's AI Research group (FAIR). It provides a flexible platform for building and training deep neural networks, with a focus on dynamic computation graphs that allow for more efficient memory usage and faster experimentation.

PyTorch provides several key features that make it a popular choice for deep learning:

- Dynamic computation graphs: Unlike some other deep learning frameworks, PyTorch uses dynamic computation graphs, which means that the graph is constructed on the fly as the program runs. This allows for more flexibility in how models are constructed, and makes it easier to experiment with different architectures and hyperparameters.

- GPU acceleration: PyTorch has built-in support for GPU acceleration, which allows deep learning models to be trained much faster than on a CPU. PyTorch makes it easy to move tensors (the primary data structure in PyTorch) between CPU and GPU memory, and to parallelize operations across multiple GPUs.

- TorchScript: PyTorch includes a tool called TorchScript, which allows models to be compiled into a standalone executable format that can be run on devices that do not have PyTorch installed. This makes it easier to deploy models to production environments, such as mobile devices or embedded systems.

- Strong community support: PyTorch has a large and active community of developers who contribute to the library and provide support on forums such as GitHub and Stack Overflow. This makes it easier to find help when encountering issues, and to share knowledge and best practices with other developers.

In the project, PyTorch was used for building and training deep learning models, along with TensorFlow. The choice of framework often depends on the specific requirements of the project, as well as the developer's personal preference and experience. PyTorch was chosen in part due to its flexible and dynamic nature, which made it easier to experiment with different architectures and hyperparameters.

CODING AND TESTING

1. OBJECT DETECTION

1.1. Image Processing:

```
import cv2
import numpy as np
import pickle
import pandas as pd
from ultralytics import YOLO
import cvzone

The implementation of the Smart Parking System utilizing the YOLOv8 model for vehicle detection and dynamic pricing algorithms marks a significant advancement in parking management technology. Through real-time analysis of video input, the system accurately identifies occupied and vacant parking slots, enhancing operational efficiency.

The dynamic pricing mechanism ensures optimal utilization of parking spaces by adjusting prices based on factors such as demand, time of day, and special events. This not only maximizes revenue potential but also promotes fairness and competitiveness in pricing.

Moreover, the system provides valuable insights to users by displaying the number of available parking slots and their corresponding status. This empowers drivers to make informed decisions, reducing congestion and improving overall parking experience.

In conclusion, the Smart Parking System represents a comprehensive solution for modern parking facilities, offering efficient management, revenue optimization, and enhanced user satisfaction. With its integration of advanced technologies and dynamic features, it sets a new standard for intelligent parking solutions in urban environments.

CONCLUSION AND FUTURE ENHANCEMENTS

Conclusion

In this paper, a smart parking management system using AI technique was presented. The implemented system recognizes the vehicle number and uses it as an object ID, and tracks the vehicle by applying YOLO technology. Training and learning algorithms based on CNN deep learning algorithm were applied to detect whether a vehicle was parked or an accident occurred. A number of experiments was conducted to check the detection accuracy and it was confirmed that the deep learning algorithm works effectively after training reasonable number of images. Experimental results show that the detection accuracy of parking and accident detection increases as the number of training images increases. The accident detection needed more training images because it has more diversity. In both experiments, greater that 95% of detection accuracy was observed. The smart parking app allows drivers to easily check parking information and accident information. As a conclusion, the system implemented in this study can be utilized as an AI-based unmanned parking management system.

The implemented system used a simulated parking lot. Therefore, future research following this study is to implement a system for an actual parking lot. In addition, research to improve the detection accuracy and the processing speed will be performed.
